Cooling Water Corrosion
Corrosion

Program Topics:

- Consequences
- Mechanisms
- Factors Affecting
- Metal Failures
- General Control

- Inhibitors
- Program Choice
- Control
- Pretreatment
- Norms & Economics
Consequences of Corrosion

- Reduced Heat Transfer (Lost Efficiency)
- Increased Cleaning (Added Costs and Hassle)
- Equipment Repair and Replacement (Lost Revenue)
- Process or Water-Side Contamination (Poor Product Quality)
- Unscheduled Shutdown (Lost Revenue)
Introduction

Corrosion -

An electrochemical process in which a metal in its elemental form returns to its native (i.e., oxidized) state.
The following elements are required for corrosion to occur:

- A corrodable surface - one with electrons to lose
- A difference in potential - a driving force for the electrons
- An electron acceptor - a place for the electrons to go
- An electrolyte, to close the circuit - conditions conducive for electron flow
The Corrosion Cell

The Rate of Corrosion is Determined by Reactions at the Cathode:

- Size of the Cathode
- Amount of Oxidizer at the Cathode
- Polarization (the size of the potential difference)
- Temperature
- Water Velocity
- pH
- Dissolved Gases
The Corrosion Cell

The Type of Corrosion is Determined by the Environment at the Anode:

- Chemistry Anomalies
  - Differential Ion Cells
  - Differential Oxygen Cells
- Surface Anomalies
  - Deposits
  - Surface Imperfections
  - Dissimilar Metals

Types of Cooling Water Corrosion

- General Etch
- Concentration Cell Corrosion
- Cracking
- Mechanical Damage
**Types of Cooling Water Corrosion**

- **General Etch**

  Metal loss in which a given area is alternately a cathode and an anode. Metal loss occurs uniformly over the entire surface.

  This is the preferred type of corrosion.
Types of Cooling Water Corrosion

- Concentration Cell Corrosion
  
  A localized attack caused by a chemical anomaly.
  
  - Crevice Corrosion
  - Under Deposit Corrosion
  - Tuberculation
  - Biologically Induced Corrosion
  - Acid or Alkaline Corrosion
Types of Cooling Water Corrosion

- **Tuberculation**

Highly structured mounds of corrosion products that cap localized regions of metal loss

- **Metal loss region**
- **Fracture in crust**
- **Fluid filled cavity**
  (Fe²⁺, Cl⁻, SO₄²⁻)
- **Core (friable)**
  - Ferrous Hydroxide
  - Iron Carbonate
  - Phosphates, etc.
- **Shell (brittle)**
  - Magnetite - black
- **Crust (friable)**
  - Hematite - red, brown, orange
  - Carbonate - white
  - Silicates - white

Corroding floor

Metal loss region
METAL

WATER
Types of Cooling Water

Corrosion

- Cracking

Failures caused by the combined effects of corrosion and metal stress. Initiate on the surface exposed to the corrodant, and propagate into the metal in response to the stress state. The critical factors are:

- Sufficient Tensile Stress
- A Specific Corrodant
Types of Cooling Water

Corrosion

Mechanical Damage

- Corrosion Fatigue
- Erosion - Corrosion
- Cavitation
- Dealloying
General Methods for Corrosion Inhibition

- Use Corrosion Resistant Materials
- Apply Inert Barrier or Coating
- Use Cathodic Protection
- Adjustments to Water Chemistry
- Application of Corrosion Inhibitors
Chemical Corrosion Inhibitors

Mechanism

- Principally Anodic
- Principally Cathodic
- Both Anodic and Cathodic
Anodic Inhibitors

Function by adjusting the chemistry at the anode (point of high potential)

- Chromate
- Molybdate
- Nitrite
- Ortho Phosphate (High Dose)
- Silicate
Cathodic Inhibitors

Function via reactions at the cathode (point of high pH)

\[
\text{Zn}^{2+} + 2 \text{OH}^- \rightarrow \text{Zn(OH)}_2 \\
\text{Ca}^{2+} + \text{OH}^- + \text{HCO}_3^- \rightarrow \text{CaCO}_3 + \text{H}_2\text{O} \\
\text{Ca}^{2+} + \text{OH}^- + \text{H}_2\text{PO}_4^- \rightarrow \text{CaHPO}_4 + \text{H}_2\text{O}
\]
Cathodic Inhibitors

Function by adjusting the chemistry at the cathode (point of high pH)

- Zinc
- Ortho Phosphate (low dose)
- Polyphosphate
- Phosphonates
- Calcium Carbonate
Both Anodic and Cathodic Inhibitors

- Soluble Oils

- Azole Filmers
  - Mercaptobenzothiazole (MBT)
  - Benzotriazole (BZT)
  - Tolytriazole (TT)
Program Choice

Program Selection requires that all technical, environmental and economic needs are met.

- Environmental Considerations
- Make Up Water Chemistry
- Possible Contaminants
- System Dynamics
- Other Program Needs
Feed and Control

Proper Program Maintenance requires the continuous application of the correct level of inhibitor:

- Continuous Feed
- Routine Testing
- Monitoring Program Effectiveness
  - Corrosion coupons
  - Corrators and Corrosometers
  - Total Iron, Copper, etc
  - Eddy Current Testing
Pretreatment
Pretreatment

Purpose -

- Before a new system is brought on line, or, after an acid cleaning, the system is cleaned with a chemical capable of establishing a passive (i.e., corrosion resistant) film in order to prevent initial damage.
Pretreatment

Mechanism -

- **Film Formers** - Application of high levels of phosphates (poly or ortho) establish a tough iron phosphate film which cleaning oils and residue from the surface.

- **Passivators** - Application of high levels of chromates, nitrites or molybdates establishes a tough iron oxide film which is passive to corrosion.
**Norms & Economics**

- General scale, deposit and corrosion control costs:
  
  $75-400/MM # Blowdown

- **Properly Monitored Corrosion Rates**
  
  - <5 mpy mild steel (general etch)
  - <1 mpy mild steel (with chromate)
  - <0.2 mpy copper and copper alloys
  - <0.1 mpy on exotic alloys
